- Summary

The Fault-Tolerant Facility Placement Problem (FTFP)

Given

- F, a set of sites can have facilities built,
- C, a set of clients with demands,
- r_i , demand for client j,
- f_i, cost to build one facility at site i,
- d_{ij}, cost to connect one demand from client j to facility at site
 i. Distances form a metric.

Find

- y_i, number of facilities to build at each site,
- x_{ij} , number of connections between site i and client j.

Goal: Minimize the total cost of opening facilities, sum of f_iy_i and connecting clients, sum of $d_{ii}x_{ii}$.

Main Result

An LP-rounding algorithm with approximation ratio 1.575.

Related Problems

- The Uncapacitated Facility Location problem (UFL), all $r_i = 1$, best approximation ratio 1.488 (Li'12).
- The Fault-tolerant Facility Location problem (FTFL), all $y_i \le 1$, best approximation ratio 1.7245 (Byrka *et al.*'10).
- The Fault-tolerant Facility Placement problem (FTFP), best approximation ratio 1.575 (this paper), matching the best known LP-based approximation ratio for UFL.

The Uncapacitated Facility Location Problem (UFL)

All demands are 1, each site can open only one facility.

Solution

The LP Formulation for FTFP

- y_i represent the number of facilities built at site i.
- x_{ij} represent the number of connections from client j to facilities at site i.

minimize
$$\sum_{i \in \mathbb{F}} f_i y_i + \sum_{i \in \mathbb{F}, j \in \mathbb{C}} d_{ij} x_{ij}$$
 (1)
subject to $y_i - x_{ij} \ge 0$ $\forall i \in \mathbb{F}, j \in \mathbb{C}$
 $\sum_{i \in \mathbb{F}} x_{ij} \ge r_j$ $\forall j \in \mathbb{C}$
 $x_{ij} \ge 0, y_i \ge 0$ $\forall i \in \mathbb{F}, j \in \mathbb{C}$

maximize
$$\sum_{j \in \mathbb{C}} r_j \alpha_j$$
 (2)
subject to $\sum_{j \in \mathbb{C}} \beta_{ij} \leq f_i$ $\forall i \in \mathbb{F}$
 $\alpha_j - \beta_{ij} \leq d_{ij}$ $\forall i \in \mathbb{F}, j \in \mathbb{C}$
 $\alpha_j \geq 0, \beta_{ij} \geq 0$ $\forall i \in \mathbb{F}, j \in \mathbb{C}$

Techniques

- Demand Reduction.
- Adaptive Partition.

Demand Reduction

- Reduce a general FTFP instance to a restricted FTFP instance with $r_i \leq |\mathbb{F}|$ for all clients j.
- Solving LP to obtain (x^*, y^*) .
- Round down $(\mathbf{x}^*, \mathbf{y}^*)$ to obtain integral part $(\hat{\mathbf{x}}, \hat{\mathbf{y}})$. Define $\hat{r}_j = \sum_i \hat{x}_{ij}$.
- The rest form fractional part $(\dot{\mathbf{x}},\dot{\mathbf{y}})$. Define $\dot{r}_j=r_j-\hat{r}_j$.
- Both parts are feasible and optimal for their respective FTFP instances $\hat{\mathcal{I}}$ and $\dot{\mathcal{I}}$.

Claim

 $\dot{r}_j \leq |\mathbb{F}|$ for all clients j in $\dot{\mathcal{I}}$.

Theorem

Theorem

Given any ρ -approximation algorithm \mathcal{A} for the restricted FTFP problem with $r_j \leq |\mathbb{F}|$, if ρ is an upper bound on comparing algorithm's cost and the optimal fractional solution's cost, then we have a ρ -approximation algorithm for the general FTFP problem.

Adaptive Partition

- Begin with a fractional complete solution (x, y).
- In the partitioned solution,
 - Each site i has facilities μ .
 - Each client j has r_j demand points ν .
 - Each facility μ has fractional opening \bar{y}_{μ} .
 - Each demand point connects to each facility with value $\bar{x}_{\mu\nu}.$
- The partitioned solution $(\bar{\mathbf{x}}, \bar{\mathbf{y}})$ satisfies a number of properties.
 - y_i^* distributed among facilities at site i,
 - x_{ij}^* distributed among sibling demands of client j,
 - $\bar{x}_{\mu\nu} = \bar{y}_{\mu}$ or 0 (completeness),
 - \bullet Each demand ν is assigned to a primary demand κ with a low cost.

An Example of Partition
